## Picolinic acid: A Potential Therapeutic Against Pandemic Viruses

# Unique New Species of Marine Bacteria Discovered in Deep-Sea Cold Seep

#### Alphine and Artic Microbes Break Down Plastics

### A Probiotic to Protect Caribbean Corals

Researchers from the Indian Institute of Science, Bangalore, have demonstrated Picolinic acid's (PA) potential against pandemic viruses, specifically SARS-CoV-2 and Influenza A, through broad-spectrum antiviral activity and immune response enhancement. The study emphasises PA's promising therapeutic role and its unique mechanism targeting viral entry and immune modulation.[1]

According to the reports researchers have discovered a new deep-sea bacterial strain,

Poriferisphaera hetertotrophicis, which is unique for its budding division model and plays a significant role in nitrogen assimilation. The bacteria also live symbiotically with a bacteriophage that further facilitates nitrogen metabolism. [2]

According to the reports researchers identified cold-adapted microbes that degrade certain plastics at low temperatures, potentially saving energy in industrial recycling. [3]

According to the reports a bacterial strain from healthy corals could slow the progression and prevent transmission of the destructive stony coral tissue loss disease in the wild. [4]
